

## C Programming Lecture 9

Tuesday, 18 June 2024

8:18 PM

0x100 0x101 ... 0x109 0x10A 0x10B ... 0x10E  
0x110 0x111

int \*p;

p = p + 5;

↑  
0x100

100 + 5 (sizeof(int))

Pointer arithmetic :-

int \*p, \*q;

q = p + 5; → 120

printf("%d", q - p);

(5)

Size of (int) = 4

p = 0x100 → 100

q = 0x114 → 120

E ← 15  
10 ← 16  
11 ← 17  
⋮  
14 ← 18

$$q - p = \frac{120 - 100}{\text{sizeof(int)}} = (5)$$

Arrays in C

- Sequential collection of elements of same data type.
- As they are stored sequentially in memory, it gives the advantage to access any element in constant time using the index.

For a type T, T[size] is the type, "array of size elements of type T".

The elements are indexed from 0 to size-1.

For example:

```
int arr[2]; // an array of two integers: arr[0], arr[1]
char* p[4]; // an array of four pointers to char: p[0], p[1], p[2], p[3]
```

An array can be initialized by a list of values: ✓

- int arr[] = {4, 3, 2, 1}; ✓
- char p[] = {'x', 'y', 'z'}; ✓

Example: Correct or incorrect:

1. int arr1[3] = {1, 2, 3, 4}; ✓
2. int arr2[6] = {1, 2, 3, 4}; ✓
3. int arr3[6] = arr2; ✗

```
int x, y, z;
```

```
int a[3];
```

$i^{th} \rightarrow a[i-1]$   
n elements  
 $a[0] \rightarrow a[n-1]$

$2^{nd} \rightarrow a[2] = 100 + 2 \times 4$   
 $\downarrow$   
 $3^{rd} \text{ element}$       $(i-1)$       $\downarrow$       $\text{size of (int)}$   
 $i^{th}$

[ ] ( ) ✓

char. a, b, c, d;

char \* p[4];

p is an array of 4 character pointers

a [a] 1B  
0x200

b [b] 1B  
0x300

c [c] 1B  
0x400

d [d] 1B  
0x500

sizeof (pointer) = 8

P[0] = &a, P[1] = &b, P[2] = &c, P[3] = &d

\* P[2] = 'c'

## Pointers and Arrays

The name of an array can be used as a pointer to its initial elements,

```
int v[] = {1, 2, 3, 4};
int* p1 = v;           // pointer to initial element
int* p2 = &v[0];       // pointer to initial element
int* p3 = v+4;
```

```
#include<stdio.h>
```

```
void main() {
```

```
    int arr[5] = {1, 2, 3, 4, 5};
```

```
    int* p = arr;
```

```
    for(int i = 0; i < 5; i++)
```

```
        printf("%d ", *(p+i));
```

```
}
```

1 2 3 4 5

\*p, \*(p+1)

\*(p+2) \*(p+3)

\*(p+4)

arr

p 100 int \*

sizeof(int) = 4B

\*(p2+2) = 3

\*(p3 + (p1 - p2) - 2) = 3

\*(p3-2) = 3

```
int a[5] = {1, 2, 3, 4, 5}
```

$$a[2] \equiv * \underline{\underline{a+2}}$$
$$a[i] \equiv * (a+i)$$

printf ("%d", a[4]);  
 ↓      ↗  
 \*(a+4)

$$a[3] = 7$$
$$* (a+3) = 7$$
$$\begin{aligned} (a+3) &= 7 \\ \underline{\&a[2]} &= 108 \quad \begin{array}{l} \nearrow \&3 = 108 \\ \nearrow \&(*108) \end{array} \\ &= \underline{\underline{a+2}} = \underline{\underline{108}} \end{aligned}$$

$$a[0] = *(a+0) \\ = *a$$

```
printf("%d", a[i]);
```

### Multidimensional Arrays

Arrays of arrays are the multidimensional arrays

```
int marr[3][5]; // 3 arrays with 5 elements each
```

```
int arr[3][2] = {{0,1}, {2,3}, {4,5}};  
for (int i = 0; i < 3; i++) {  
    for (int j = 0; j < 2; j++)  
        printf("%d", arr[i][j]);  
}
```

```
int a[3][4];
```

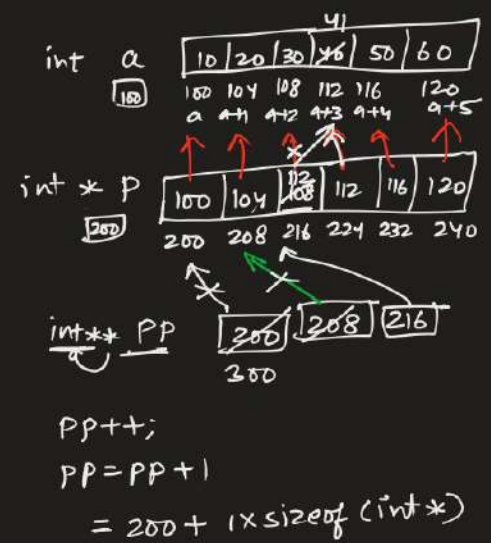

```

eg. int main() {
    int a[] = {10, 20, 30, 40, 50, 60};
    int *p[] = {a, a+1, a+2, a+3, a+4, a+5};
    int **pp = p;
    pp++;
    printf("%d, %d, %d", pp-p, *pp-a, **pp);
    *pp++;
    printf("%d, %d, %d", pp-p, *pp-a, **pp);
    ++*pp;
    printf("%d, %d, %d", pp-p, *pp-a, **pp);
    ++**pp;
    printf("%d, %d, %d", pp-p, *pp-a, **pp);
    return 0;
}

```

right to left  
post inc/dec > pre inc/de = \*

### Example (GATE CS 2024 Set 2)

What is the output of the following C program?

```
#include <stdio.h>
int main() {
    double a[2]={20.0, 25.0}, *p, *q;
    p = a; ✓
    q = p + 1; ✓
    printf("%d,%d", (int)(q - p), (int)(*q - *p));
    return 0;}
```

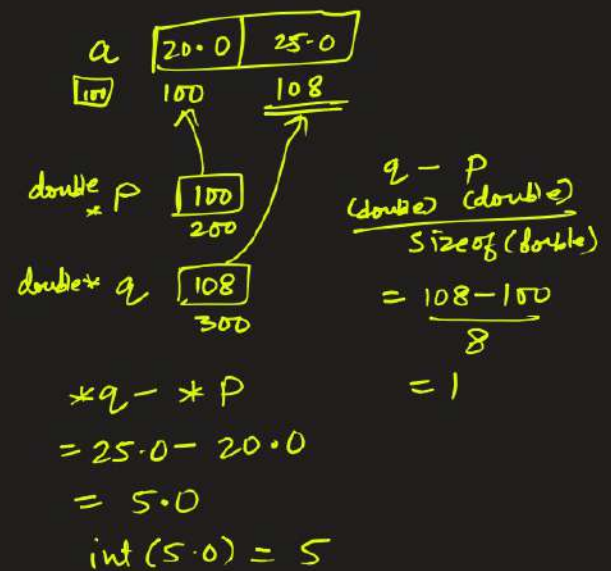

1      5

A 4,8

☒ B 1,5

C 8,5

D 1,8

### Example (GATE CS 2022)

What is printed by the following ANSI C program?

```
#include <stdio.h>
int main(int argc, char *argv[])
{
    int x = 1, z[2] = {10, 11};
    int *p=NULL; p=&x;
    *p=10;
    p = &z[1];
    *(&z[0]+1) += 3;
    printf("%d, %d, %d \n", x, z[0], z[1]); return 0;
}
```

- A 1, 10, 11
- B 1, 10, 14
- C 10, 14, 11
- ☒ D 10, 10, 14

$\&z[0]$   
 $200 + 1$   
 $\downarrow$   
 $*204$

$\&z[1]$   
 $= \&(*z+1)$   
 $= \underline{\underline{z+1}}$

## Multidimensional Arrays

Arrays of arrays are the multidimensional arrays

```
int marr[3][5]; // 3 arrays with 5 elements each
```

```
int arr[3][2] = {{0,1}, {2,3}, {4,5}};
for (int i = 0; i < 3; i++) {
    for (int j = 0; j < 2; j++) {
        printf("%d, ", arr[i][j]);
    }
}
```

→ rows  
→ columns  
→ 0, 1, 2, 3, 4, 5

There are two methods of storing multidimensional arrays:

Row major order: The elements are arranged consecutively along the row.

|         |                 |                 |                 |                 |                 |                 |                 |                 |                 |
|---------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| Address | 0               | 1               | 2               | 3               | 4               | 5               | 6               | 7               | 8               |
| Element | a <sub>11</sub> | a <sub>12</sub> | a <sub>13</sub> | a <sub>21</sub> | a <sub>22</sub> | a <sub>23</sub> | a <sub>31</sub> | a <sub>32</sub> | a <sub>33</sub> |

Address[row][column] = Base address + row\*num\_columns\*element\_size + column\*element\_size

|      | col0 | col1 |     |     |     |     |     |     |
|------|------|------|-----|-----|-----|-----|-----|-----|
| row0 | 0    | 1    | 100 | 104 | 108 | 112 | 116 | 120 |
| row1 | 2    | 3    | 0   | 1   | 2   | 3   | 4   | 5   |
| row2 | 4    | 5    |     |     |     |     |     |     |

int a [3][4] = { {1,2,3,4}, {5,6,7,8}, {9,10,11,12} }

# rows = 3

# columns = 4

every row contained 4 columns

Base address (BA) = 100

address a[2][2] = ?

|          | col0 | col1 | col2 | col3 |
|----------|------|------|------|------|
| a: row 0 | 1    | 2    | 3    | 4    |
| row 1    | 5    | 6    | 7    | 8    |
| row 2    | 9    | 10   | 11   | 12   |

2 rows completely passed  
in the 3<sup>rd</sup> row, 2 elements passed and we are at 3<sup>rd</sup> element

$$\text{Total elements passed} = \underbrace{2}_{\text{\# rows passed}} \times \underbrace{4}_{\text{\# columns}} + \underbrace{2}_{\text{\# columns passed in 3rd row}} = 10$$

Example (GATE CS 2002):

Consider the following declaration of a 'two-dimensional array in C:

char a[100][100];

100 rows, 100 columns

→ row-major order

Assuming that the main memory is byte-addressable and that the array is stored starting from memory address 0, the address of a[40][50] is

a) 4040

☒ b) 4050

c) 5040

d) 5050

$$\begin{aligned}\text{address of } a[\underline{40}][\underline{50}] &= BA + (40 \times 100 + 50) * 1 \\ &= 0 + 4000 + 50 \\ &= \underline{\underline{4050}}\end{aligned}$$

**Column major order:** The elements are arranged consecutively along the column.

| Address | 0        | 1        | 2        | 3        | 4        | 5        | 6        | 7        | 8        |
|---------|----------|----------|----------|----------|----------|----------|----------|----------|----------|
| Element | $a_{11}$ | $a_{21}$ | $a_{31}$ | $a_{12}$ | $a_{22}$ | $a_{32}$ | $a_{13}$ | $a_{23}$ | $a_{33}$ |

$$\text{Address}[\text{row}][\text{column}] = \text{Base address} + \text{column} * \text{num\_rows} * \text{element\_size} + \text{row} * \text{element\_size}$$

int  $a[3][4] = \{ \{1, 2, 3, 4\}, \{5, 6, 7, 8\}, \{9, 10, 11, 12\} \}$ , assume CMD

rows      columns

Find the address of  $a[2][2]$

# elements passed

$$= 2 \text{ columns} * 3$$

+ 2 rows in column '2'

$$= \underline{\underline{8}}$$

$$\therefore \text{Address of } a[2][2] = 100 + 8 \times 4$$

$$= \underline{\underline{132}}$$

### Example [H/w]

Consider a two-dimensional array A with 3 rows and 4 columns stored in memory in column-major order. Given the base address of the array A is 2000, and indices  $i = 1$  (row index) and  $j = 2$  (column index), what is the address of the element  $A[1][2]$ ? (Assume the array stores integers which hold 4 B of memory)
